INTRODUCTION

Assistive devices—such as wheelchairs, scooters, canes, crutches, and walkers—are effective ways to alleviate the impact of mobility limitations for many people, allowing improved ambulation and independence. Because the U.S. population is aging, the use of assistive devices by people with mobility impairments is of increasing importance. Assistive technology may be responsible for the observed reduction in the level of activity limitation at older ages (Manton, Corder, and Stallard, 1993).

The use of mobility devices has grown in recent years (LaPlante, Hendershot, and Moss, 1992), with the populations using wheelchairs and walkers doubling from 1980 to 1990. Crutch and cane use also increased by 14 percent and 53 percent, respectively, over this period. Growth in the usage of these devices continued from 1990 to 1994 (Russell, Hendershot, LeClere, Howie, and Adler, 1997), far exceeding what could be attributed to the aging of the population. It is likely that improved survival of trauma patients has also contributed to the growth in mobility device use. However, significant improvements in the design of mobility devices, both in function and image, have also fueled this growth. While financing may have become more available, it remains the case that about half of people or their families pay for devices solely on their own. The unmet need for devices is substantial, with the primary barrier being that people simply cannot afford to purchase them.

Although mobility device users represent only a relatively small minority of the population with disabilities, their importance transcends their numbers. Mobility devices, especially wheelchairs, are highly visible signs of disability; they have even become symbols in themselves of the concept of disability. Understanding the magnitude and characteristics of the population using these assistive technologies is therefore of particular importance.

For mobility devices to be used effectively, the environments in which they are used must be accessible. Yet, there is little data on the extent of accessibility barriers faced by people who use these devices.

This report focuses on the population using devices, providing a detailed profile of their demographic characteristics; health and disability status, including diagnoses and impairments, physical functioning, and activities of daily living; and health insurance status. More significantly, the report addresses the accessibility of mobility device users' homes and larger environments, demonstrating that improvements in physical accessibility remain a priority for millions of mobility device users who still experience accessibility barriers.

HIGHLIGHTS

- Just over 6.8 million community-resident Americans use assistive devices to help them with mobility. This group comprises 1.7 million wheelchair or scooter riders and 6.1 million users of other mobility devices, such as canes, crutches, and walkers.
- High levels of mobility device use are observed among African Americans and Native Americans. Asians and Pacific Islanders are the racial group with the lowest device use.
- Less than one-fifth of working-age wheelchair and walker users are employed; the employment rate for crutch users is more than twice as high.
- More than four-tenths of mobility device users are unable to perform their major activity.
- Nearly all wheelchair users report trouble walking, and more than three-quarters are unable to walk a quarter of a mile.
- Almost one-third of mobility device users need assistance from another person in one or more of the Activities of Daily Living (ADL), compared to less than 1 percent of non-users.
- Two-thirds of mobility device users have limitations in one or more of the Instrumental Activities of Daily Living (IADL).
- Osteoarthritis is by far the most prevalent condition associated with mobility device use, affecting 1.2 million mobility device users as the primary cause of disability.
- Stroke and osteoarthritis are the two most prevalent primary conditions among wheelchair and scooter users.
- About half of wheelchair users must use steps to enter or exit their homes. A similar fraction report having difficulty entering or leaving the home.
- Four-fifths of wheelchair users report that their local public transportation system is difficult to use or to get to.
- Among children who use wheelchairs, almost six-tenths are covered under Medicaid. Among working-age wheelchair users, four-tenths are covered under Medicare and three-tenths under Medicaid.

DATA SOURCE AND ACCURACY

The National Health Interview Survey (NHIS) is a nationally representative household survey conducted annually by the Census Bureau for the National Center for Health Statistics, part of the Centers for Disease Control and Prevention (CDC). Respondents to the 1994 and 1995 NHIS also took part in two supplemental surveys, known collectively as the National Health Interview Survey on Disability (NHIS-D). Developed and funded by a consortium of federal agencies and the Robert Wood Johnson Foundation, the NHIS-D was designed to gather detailed data on the U.S. community-resident population with disabilities (National Center for Health Statistics, 1998).

In Phase I of the NHIS-D, which was administered at the same time as the NHIS core, 202,560 persons were screened for any indication of disability, using an extensive set of criteria including functional limitation, specific disabling diagnoses, perception of disability, and use of disability-related services. A complex set of eligibility criteria was used to identify a sample of persons who fell within one or more of several conceptual or programmatic definitions of disability; these persons were to be interviewed again at a later date as part of the second phase of the NHIS-D.

The Phase II questionnaire, known as the Disability Followback Survey (DFS), contained detailed questions on employment, use of services, benefits, transportation, personal assistance needs, housing characteristics, environmental barriers, and participation in social activities. Data collection began in September 1994 and concluded in April 1997, with interviews taking place between 7 and 26 months following the Phase I interview (median lag between interviews was 13.6 months). The Phase II sample numbers 32,788 persons.

Questions on mobility device use were asked in both phases of the NHIS-D. The bulk of the statistics in this report (those in Tables 1–10 and 14, all of the text tables, and Figures 1–20 and 23–24) are based on the authors' tabulations of the Phase I data. Data from the NHIS core were also used in these tabulations, and the NHIS Family Resources Supplement is the source of the health insurance data in Table 14 and Figures 23–24.

Statistics on accessibility features and problems (Tables 11–13 and Figures 21–22) are based on tabulations of data from Phase II, the Disability Followback Survey. In these tables, the responses to the mobility device questions from Phase II have been used to establish the relevant populations.

The vast majority (96 percent) of those identified in Phase I as mobility device users were selected for the Phase II sample. All long-term wheelchair, scooter, walker, and crutch users were automatically deemed eligible to participate in the DFS (device use expected to last at least one year from the date of the Phase I interview); respondents with one or more severe (or two or more moderate) mobility-related functional limitations were also selected. As a result, nearly all (99 percent) of the Phase I wheelchair and scooter users were eligible for Phase II, as were 98 percent of walker users. Thus, no significant biases are expected in the DFS analysis due to the selection criteria, except for a possible under-representation of some short-term device users.

It is important to note that residents of institutions, such as nursing homes, prisons, and larger residential facilities for persons with mental or physical disabilities, are not sampled in the NHIS. Thus, statistics presented in this report represent only the non-institutional, community-resident population. A small number of respondents moved into institutions during the months between the Phase I and II interviews; although these people have been included in the DFS, the sample essentially remains representative of the non-institutional population only.

Because the estimates in this report are based on a sample of the population, they are subject to sampling error. All sampling errors have been calculated directly using SUDAAN, which takes into account the complex design of the survey. In the data tables, estimates with low statistical reliability (standard error greater than 30 percent of the estimate) are flagged with an asterisk. All comparisons mentioned in the text have been tested for statistical significance, and, unless otherwise stated, are significant at the 95 percent confidence level or greater ($p \leq .05$).

POPULATION ESTIMATES AND SOCIODEMOGRAPHIC COMPARISONS

Just over 6.8 million Americans living outside of institutions use assistive devices to help them with mobility. This group, which amounts to 2.6 percent of the non-institutional population, comprises 1.7 million wheelchair or scooter riders (0.6 percent of the population) and 6.1 million (2.4 percent of the population) users of other mobility devices, such as canes, crutches, and walkers (see Table 1). Canes are by far the most widely used mobility devices: 4.8 million Americans use them, or 70 percent of mobility device users.¹ Walker use is reported by 1.8 million persons and crutches are used by 566,000 persons.²

Of the 1.7 million wheelchair/scooter users, the vast majority (90 percent, or 1.5 million persons) use manual wheelchairs. Only 155,000 community-resident Americans use electrically powered wheelchairs, and only 142,000 use scooters. Some 291,000 persons use either (or both) of these motorized devices.

Tables 1 through 4 present prevalence esti-

mates of mobility device use broken down by the demographic and socioeconomic characteristics of device users. In Table 1, basic sociodemographic and economic breakdowns are provided for all devices, with separate prevalences for manual wheelchairs, electric wheelchairs, and scooters, and for all three devices combined. Separate prevalence estimates are also provided for cane, crutch, and walker use, as well as for those three devices combined. Tables 2 through 4 provide more extensive sociodemographic and economic data, but device use is broken down less finely: wheelchairs (manual, electric, or both), scooters, canes, crutches, walkers, and any of the above.

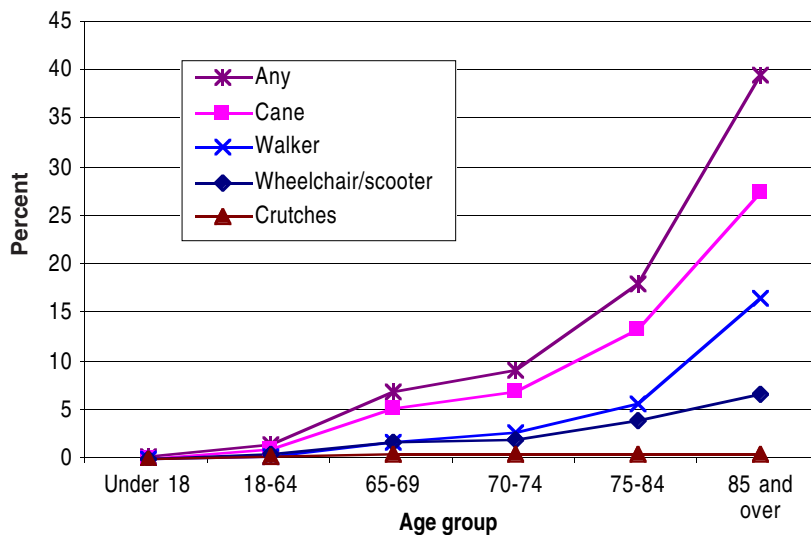

Age and Gender

As illustrated in Figure 1, the proportion of the population using mobility devices increases sharply with age. While only 0.2 percent of children under age 18 use any kind of mobility device, that

proportion increases seven-fold, to 1.5 percent, among those of working age (see Table A). Among the elderly, the 14.0 percent overall rate of mobility device use is almost a factor of 10 times that of working-age adults. Just under 40 percent of persons aged 85 or over use mobility devices.

Cane use is especially prevalent among the elderly, at 10.2 percent of the population aged 65 or over. Some 4.6 percent of elderly persons use walkers, and 3.0 percent use wheelchairs or scooters. In all, nearly two-thirds (64.0 percent) of mobility device use is by

Figure 1. Proportion of population using mobility devices, by age and device.

¹ The mobility device question in the NHIS-D Phase I asks whether anyone in the family uses any in a list of devices “to get around.” Without any contextual reference to mobility impairment, some blind people using white canes reported themselves as cane users. While it could be argued that a white cane is indeed a mobility device, the authors of this report chose not to broaden the scope of the analysis beyond persons with specifically mobility-related impairments. Thus, respondents identified as using white canes, as ascertained by a question asked only about persons with visual impairments, have not been counted as cane users, even when the interviewer was told that they use a cane “to get around.” The population estimate of 4,755,000 cane users would have been increased by 75,000 to 4,830,000 if white cane use had not been excluded.

² The NHIS-D Phase I questionnaire also asks about the use of medically prescribed shoes, but these have not been included as mobility devices for the purposes of this report.

Table A. Number of persons and proportion of population using mobility devices, by age and device used.

	All Persons		Under 18		18–64		65 and over	
	Number (1000s)	Proportion (percent)	Number (1000s)	Proportion (percent)	Number (1000s)	Proportion (percent)	Number (1000s)	Proportion (percent)
Any mobility device	6,821	2.62	145	0.21	2,310	1.45	4,366	13.97
Wheelchair or scooter	1,679	0.64	88	0.12	658	0.41	933	2.99
Wheelchair	1,599	0.61	88	0.12	614	0.39	897	2.87

Cane	4,755	1.82	19 *	0.03	1,535	0.96	3,200	10.24
Crutches	566	0.22	36	0.05	375	0.24	155	0.50
Walker	1,820	0.70	27	0.04	373	0.23	1,421	4.55

*Standard error exceeds 30 percent of the estimate.

persons aged 65 or over. Over three-quarters (78.1 percent) of walker users and just over two-thirds (67.3 percent) of cane users are elderly, as are 55.6 percent of wheelchair/scooter users. The vast majority (72.6 percent) of crutch users, however, are non-elderly.

Among working-age adults, canes and wheelchairs are the most prevalent mobility devices, used by 1.0 percent and 0.4 percent, respectively, of the population aged 18–64. Among youth, wheelchairs are the most prevalent, at 0.1 percent of the population.

It is interesting to note that, although the proportion of the population using wheelchairs or scooters increases dramatically with age, the increase is far more pronounced for manual wheelchairs than for motorized devices. As shown in Figure 2, the rate of manual wheelchair use among the elderly (2.76 percent) is nearly 8 times that for working-age adults (0.35 percent). But the rate for motorized device use (electric wheelchair or scooter) among the elderly (0.35 percent) is only 3.5 times that for working-age adults (0.10 percent). In fact, a substantial majority (62.2 percent) of motorized device users

are non-elderly, and more than two-thirds (69.7 percent) of electric wheelchair users are non-elderly.

As Table B shows, a majority (58.5 percent) of mobility device users are female, with 3.0 percent of the total female population using one or more of these devices, compared to 2.2 percent of males. Since mobility device use is much more prevalent among the older age groups, and since women have greater longevity than men, it is not surprising that more women than men must rely on assistive devices to help with mobility. The female majority holds among wheelchair/scooter users (58.8 percent), cane users (57.6 percent), and especially

Figure 2. Proportion of population using manual wheelchair vs. motorized device, by age.

Table B. Number of persons and proportion of population using mobility devices, by gender and device used.

	All Persons		Males		Females		
	Number (1000s)	Proportion (percent)	Number (1000s)	Proportion (percent)	Number (1000s)	Proportion (percent)	Percent female
Any mobility device	6,821	2.62	2,832	2.23	3,989	2.98	58.48
Wheelchair or scooter	1,679	0.64	692	0.54	987	0.74	58.78
Wheelchair	1,599	0.61	658	0.52	941	0.70	58.85
Manual wheelchair	1,503	0.58	606	0.48	897	0.67	59.68
Electric wheelchair	155	0.06	84	0.07	71	0.05	45.81
Scooter	142	0.05	60	0.05	82	0.06	57.75
Other mobility device	6,126	2.35	2,502	1.97	3,624	2.71	59.16
Cane	4,755	1.82	2,014	1.59	2,741	2.05	57.64
Crutches	566	0.22	328	0.26	238	0.18	42.05
Walker	1,820	0.70	508	0.40	1,312	0.98	72.09

among walker users (72.1 percent), with women outnumbering men by more than 2 to 1. Only among users of crutches (42.0 percent female) are men a significant majority.

When prevalence rates are stratified by age, gender differences in mobility device use become less pronounced (see Figure 3 and Table 2). Among working-age adults, the proportion of men using mobility devices is, in fact, somewhat greater than that for women (1.6 vs. 1.3 percent). Among the elderly, women are more likely to use mobility

devices than men (15.8 vs. 11.5 percent). Wheelchair use is about the same for working-age men and women (at 0.4 percent of the population for each group), but elderly women are more likely to use wheelchairs than men (3.2 vs. 2.4 percent of the population).

Race and Ethnicity

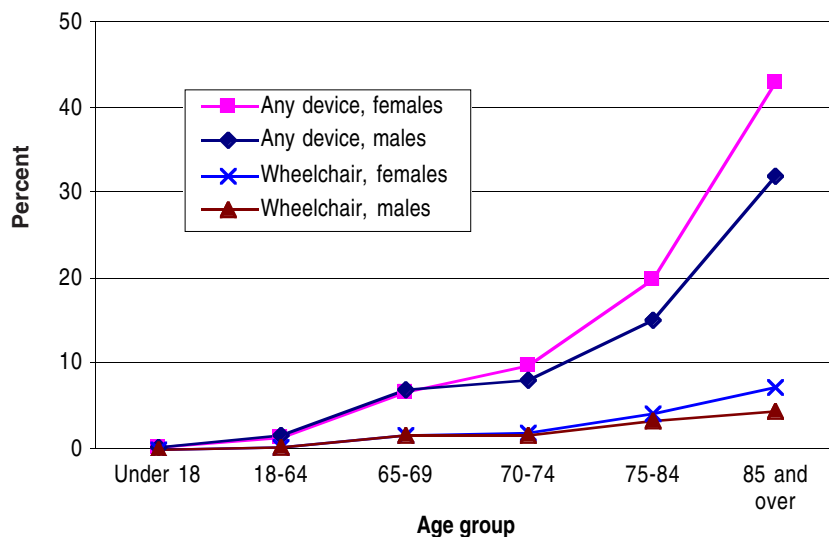

Mobility device use varies by as much as a factor of 3 among racial groups (Table 2). High levels of mobility device use are observed among African Americans, at 3.1 percent of that population, and among Native Americans, at 3.4 percent.³ The rate of mobility device use among whites is 2.6 percent. Asians and Pacific Islanders are the racial group with the lowest device use, at 1.0 percent of that population.

Ethnicity is also a significant factor. Persons of Hispanic origin are less likely to use mobility devices than those not of Hispanic origin (1.5 vs. 2.8 percent).

Different age distributions among the racial and ethnic groups may explain some of the variation. But even when only working-age persons are considered (Table 3), mobility device use remains highest for Native Americans (3.8 percent of that population) and lowest

³ The difference in rates between Native Americans and whites is not statistically significant.

Figure 3. Proportion of population using mobility devices and wheelchairs, by age and gender.

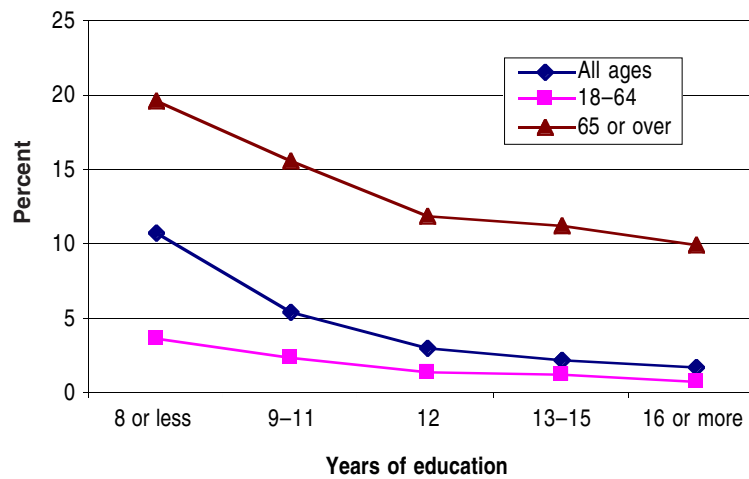

for Asians and Pacific Islanders (0.5 percent). The differences in rates are less dramatic among the elderly (Table 4); still, in this group, African Americans have a significantly higher rate of mobility device use than whites (20.6 vs. 13.5 percent).

Educational Attainment

Prevalence of mobility device use varies greatly by educational attainment (Figure 4), as do rates of disability overall (LaPlante and Carlson, 1996). The rate of mobility device use for persons without a high school education (8 years or less of education: 10.9 percent) is 6 times that of those who have completed college (16 years or more: 1.8 percent). High school graduates with no college education (12 years of education) rank in between, with 3.0 percent using mobility devices.

Since elderly Americans on average have less education than younger persons, the difference in rates is partly explained by different age distributions among those with different levels of education. Still, as shown in Figure 4, elderly persons with no high school education have twice as high a rate of mobility device use as those with college degrees (19.7 vs. 10.0 percent). Among working-age adults, 3.6 percent of those with 8 years or less of education use mobility devices, compared to 0.9 percent of those with 16 or more years.

Figure 4. Proportion of population using mobility devices, by educational attainment.

Employment and Labor Force Participation

Employment, unemployment, and labor force participation rates for working-age adults using mobility devices are shown in Table C. Using data from the NHIS core, we have classified a person as employed if he or she worked at a job or business during the two weeks prior to the interview, including unpaid work in the family farm or business but excluding work around the home. A person is considered unemployed if he or she was on layoff from a job or had no job but was actively looking for work during the two weeks prior to the interview. Anyone who is either employed or unemployed is classified as a labor force participant.

Table C. Labor force participation, employment, and unemployment, by mobility device used, ages 18-64.

	All persons	No mobility device	Any mobility device	Wheel-chair Scooter Cane Crutches Walker				
				(Percent of Population)				
In labor force	78.8	79.6	27.4	20.4	20.5	25.5	44.5	17.2
Employed	75.4	76.2	24.3	17.4	17.9 *	22.9	38.4	14.5
Unemployed	3.4	3.4	3.0	2.9	1.3 *	2.5	6.1	2.4 *
Unemployment rate †	4.3	4.3	11.1	14.4	6.3 *	10.0	13.8	14.1 *

*Estimate has low statistical reliability (standard error exceeds 30 percent of estimate).

†The unemployment rate is the proportion of labor force participants who are unemployed.

Mobility device users are much less likely to be working than those who do not use mobility devices: Only one-quarter (24.3 percent) of device users are employed, compared to three-quarters (76.2 percent) of those not using devices. Less than one-fifth of wheelchair and walker users are employed (17.4 and 14.5 percent, respectively). Cane users are slightly more likely to be employed (22.9 percent), and those using crutches are much more likely to have jobs (38.4 percent).

Labor force participation rates follow a similar pattern: 27.4 percent for mobility device users and 20.4 percent for wheelchair users, compared to 79.6 percent for non-users. Although the proportion of mobility device users who are unemployed (3.0 percent) is similar to that of those not using devices (3.4 percent), the unemployment rate (the fraction of labor force participants who are unemployed) is much higher for device users (11.1 percent vs. 4.3 percent). The unemployment rate for wheelchair users is 14.4 percent.

Family Income

Since income is highly related to educational attainment, it is not surprising that mobility device use also varies greatly with family income. As shown in Figure 5, overall mobility device use decreases by more than a factor of 6 between persons with family incomes less than \$10,000 (6.8 percent of whom are device users) and those with family incomes greater than \$35,000 (1.1 percent). Poor persons are more likely to be users of all of the var-

ious mobility devices than more wealthy individuals. For example, a person whose family income is less than \$10,000 is 4.6 times as likely to be a wheelchair user as a person whose family income is \$35,000 or more. For walker users, the ratio is more than 8 to 1.

Again, part of the variation in rates by family income has to do with age, since retired people generally have less income than working-age people. But the association between family income and mobility device use holds up when the elderly and working-age adults are considered separately (see Tables 3 and 4). Just over 4.2 percent of working-age adults with family incomes under \$10,000 use mobility devices, compared to 0.8 percent of those with incomes of \$35,000 or more, a ratio of 5.5 to 1. Among the elderly, the 24.4 percent rate of mobility device use for those with incomes under \$10,000 is 2.5 times that of those with incomes of \$35,000 or more (9.6 percent).

It is interesting to note that, although device use declines as income increases for each of the devices considered in this report, the association is not nearly as strong for motorized devices as for other devices. Electric wheelchairs and scooters are relatively expensive to purchase, and it is likely that poorer persons with mobility impairments may be unable to afford them, using manual devices instead. Figure 6 contrasts the steep decline of manual wheelchair use as income increases to the much more gradual drop in the rate of motorized device use.

Also shown in Tables 2–4 are the rates of mobility device use for persons with family incomes both

above and below the poverty line. Again, mobility device use is greater for those in poverty: 4.0 percent, vs. 2.2 percent for those living above the poverty line. Among working-age adults, the rates are 3.5 percent for those below poverty and 1.2 percent for those above. Among the elderly, 24.9 percent of those in poverty use mobility devices, compared to 12.4 percent of those above poverty.

As shown in Figure 7, mobility device users are significantly more likely to live in poverty than non-users. Overall, more than one-fifth (21.3 percent) of mobility

Figure 5. Proportion of population using various mobility devices, by family income.

Figure 6. Proportion of population using manual wheelchair vs. motorized device, by family income.

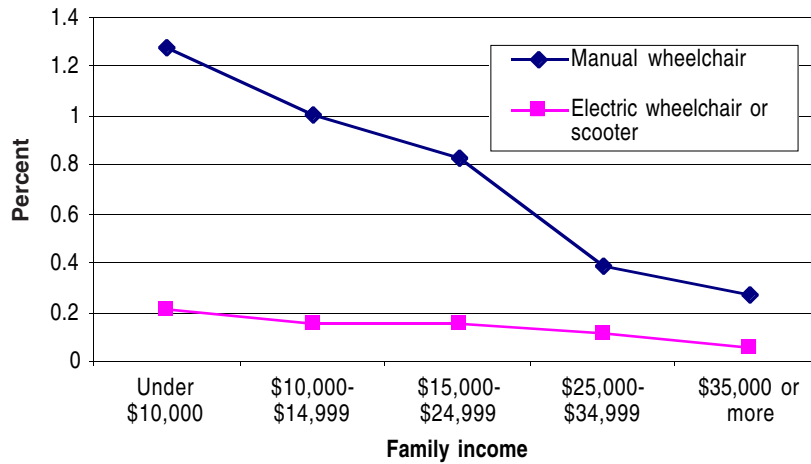

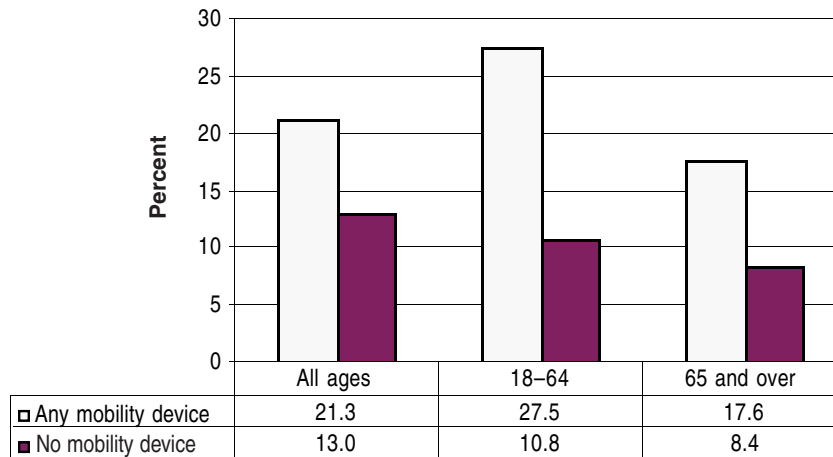

Figure 7. Poverty rate of mobility device users and non-users, by age group.

device users live in poverty, compared to 13.0 percent of the remainder of the population. Among working-age adults, mobility device users are 2.5 times as likely to live in poverty as those not using devices: 27.5 percent vs. 10.8 percent. Elderly persons using mobility devices live in poverty more than twice as often as non-users: 17.6 percent vs. 8.4 percent.

Location and Setting of Residence

The rate of mobility device use is highest in the South (2.8 percent) and lowest in the West (2.4

percent). Among elderly persons, the highest rates of mobility device use are found in the South (14.7 percent) and West (14.6 percent) and the lowest rates are found in the Northeast (12.7 percent).

Rates of mobility device use are greater in rural areas (3.2 percent) than in metropolitan areas (2.5 percent). In particular, residents of non-farm rural areas have the highest rate of mobility device use, at 3.3 percent. Some 15.2 percent of elderly persons living in rural areas use mobility devices, compared to 13.6 percent of those living in metropolitan areas in general and 12.9 percent of those living in suburbs.

HEALTH AND DISABILITY STATUS

Tables 5 through 7 present breakdowns of the population using mobility devices by health status, hospitalization history, perceived disability status, degree of activity limitation, degree and nature of functional limitation, and degree and nature of limitation in the activities of daily living (ADL) and instrumental activities of daily living (IADL). Mobility device users of all ages are included in Table 5. In Tables 6 and 7, breakdowns are provided for working-age and elderly adults, respectively.

Self-Reported Health Status

On average, people who use mobility devices are in much poorer health than those who do not use mobility devices. As Figure 8 shows,⁴ a significant majority (58.1 percent) of mobility device users report that their health is fair or poor, compared to only 8.6 percent of the population not using such devices. While only 2.0 percent of the non-device-using population report poor health status, 29.5 percent of those using mobility devices say they are in poor health.

The worst health status is found among wheelchair, scooter, and walker users, with at least one-third of each group reporting poor health (39.9 percent for wheelchair users of any age, 36.4 percent for scooter users, and 36.6 percent for walker users). Nearly two-thirds of each group (65.4 percent of wheelchair users, 63.1 percent of scooter users, and 65.1 percent of walker users) are in either fair or poor health. Only among users of crutches do a majority (54.7 percent) report their health status as good to excellent.

Among the working-age population, an even greater fraction of mobility device users report poor health (35.7 percent of those aged 18–64, compared to 2.2 percent of those not using mobility devices). Fair or poor health status is reported by 62.5 percent of working-age device users, compared to only 8.9 percent of non-users. Walker users are in especially poor health: nearly half (47.3 percent) report their health status as poor and nearly three-quarters (73.3 percent) report either fair or poor health. Scooter and cane users also report poor health quite often, 39.8 and 39.5 percent of the time, respectively.

⁴ The very small fraction of persons listed in Tables 5–7 as having “unknown” health status have been excluded from the graph in Figure 8.

Among the elderly, the gap in health status between device users and non-users is less pronounced. Some 56.8 percent of device users aged 65 and above report fair or poor health, compared to 22.6 percent of non-users. Just over one-quarter (27.0 percent) report poor health, compared to 5.8 percent of those elderly persons not using mobility devices. It is worth noting that, among the elderly, the variation in health status according to the specific device used follows a different pattern from that among the non-elderly. Elderly persons using wheelchairs report significantly worse health than users of other devices, with 45.3 percent reporting poor health and 72.5 percent reporting fair or poor health. Walker, scooter, and crutch users report the next-worst health status, with 34.4, 32.2, and 30.0 percent in poor health, respectively. Less than one-quarter (23.4 percent) of elderly cane users are in poor health.

Hospitalization History

Mobility device users are much more likely than the rest of the population to have been recently hospitalized. Nearly one-third (32.7 percent) of device users had been hospitalized in the year prior to the interview, compared to 6.8 percent of non-users. More than one-fifth (21.6 percent) of device users had been discharged from the hospital in the six months prior to the interview. These figures suggest that a significant proportion of mobility device users may be using these aids for a relatively short period of time, while recovering from surgery, injury, or disease. In particular, 44.5 percent of walker users, 43.0 percent of wheelchair users, and 35.1 percent of crutch users had been hospitalized during the 12 months prior to the interview.

Perceived Disability Status

Tables 5 through 7 present statistics on the proportion of device users who answer either of the following questions in the affirmative: “Do you consider yourself to have a disability?” or “Would other people consider you to have a disability?” We classify someone who answers either or both of these questions in the affirmative as having a perceived disability.

Two-thirds (66.7 percent) of mobility device

Figure 8. Health status of mobility device users and non-users, by age and device.

Note: Figure excludes people with unknown health status.

users have perceived disabilities (Figure 9). This proportion is almost 12 times that of the remainder of the population, only 5.8 percent of whom answer either of the perceived disability questions in the affirmative. Among users of specific devices, scooter and wheelchair users are the most likely to have perceived disabilities, with more than four-fifths of each group (89.8 and 85.0 percent, respectively) reporting that they consider themselves as having a disability or that others would do so. The close association between the use of these devices and perceived disability is not surprising, given that wheelchairs and scooters are both highly visible and very closely associated in many people’s minds with the notion of disability.

Nearly three-quarters (73.0 percent) of walker users and just over two-thirds (67.6 percent) of crutch users have perceived disabilities. Among cane users, 63.1 percent answer one or both of the perceived disability questions in the affirmative.

As Figure 9 shows, there are some significant differences in reported disability according to age, with elderly device users generally less likely to view themselves as having disabilities. While three-quarters (77.5 percent) of working-age mobility device users have perceived disabilities, only 60.7 percent of elderly device users say that they have a disability or that other people think they do. The largest gap is among cane users: 78.2 percent of working-age cane users have perceived disabilities, compared to only 56.0 percent of elderly cane users. Elderly persons may associate the need for a cane

merely with getting older, rather than assigning it the label of disability. Walker use is also more associated with perceived disability among working-age adults (81.3 percent) than among the elderly (70.7 percent).

Activity Limitation

Limitations in activity are often used to define disability. In the NHIS core, a respondent’s major activity is first identified, generally from a list of activities that are expected for someone of the respondent’s age, such as attending school, working, doing housework, or taking care of personal needs. The respondent is then asked whether an impairment or health problem keeps him or her from performing that activity; those answering affirmatively have been classified in Tables 5–7 as “unable to do major activity.” If the answer is no, the respondent is asked about any limitation in the amount or kind of the major activity that he or she can do because of an impairment or health problem; persons with such limitations are classified as “only limited in major activity” in Tables 5–7. Respondents with no major activity limitation are asked whether they are limited in any activities in any way because of an impairment or health problem; if so, they are classified as “limited only in other activity.”

The major activity for a child under 5 years of age is assumed to be play. Attending school is assumed to be the major activity for older children

Figure 9. Proportion of mobility device users and non-users with self- or other-perceived disability, by age and device.

(5–17 years of age). Adults aged 18–69 are asked about work as their major activity, unless they indicate that keeping house has been their primary activity, in which case housework is substituted for work. Persons aged 70 and over are asked about self-care (ADL) and home-management activities (IADL) as their major activity, regardless of any other activities they may engage in.

The concept of major activity limitation is therefore highly dependent upon age. Activity limitation as a whole, however, is less age dependent, since all respondents not limited in their major activity are also asked about non-major activities (“any activity in any way”).

Figure 10 shows the proportion of mobility device users and non-users who are limited in activity, whether unable to perform major activity, limited in amount or kind of major activity, or limited only in some other activity. As one might expect, mobility device users are much more likely to be limited in activity than non-users, 84.1 percent vs. 13.0 percent of persons of any age. More than four-tenths (43.2 percent) of mobility device users are unable to perform their major activity, compared to only 3.5 percent of persons not using devices. And more than two-thirds (68.9 percent) of mobility device users have some degree of limitation in their major activity, vs. 8.6 percent of non-users.

Scooter and wheelchair users are the most likely to have an activity limitation, with over nine-tenths of both groups (96.3 and 93.0 percent of persons of any age) reporting limitation. These groups also have the highest rates of major activity limitation, with 66.1 percent of wheelchair users unable to perform their major activity and an additional 21.8 percent limited in the amount or kind of major activity; for scooter users, the figures are 59.5 percent unable and 27.1 percent limited in amount or kind. Walker users have the next highest rates of activity limitation: 89.0 percent overall, with 52.6 percent unable to perform their major activity and 25.9 percent limited in the amount or kind of major activity. Although cane users are also rather likely to be limited in activity (82.8 percent), only 38.0 percent are unable to perform their major activity.

Overall activity limitation rates are quite similar for the working-age population, but the specifics are different. Because the major activity for working-age adults is defined as either work or housework, as opposed to the often less physically demanding major activities of the elderly and of children, most working-age mobility device users who are limited in activity are limited in their major activity, and most of those are unable to per-

form that activity.

Among persons aged 18–64, 89.6 percent of mobility device users are limited in activity, compared to 13.1 percent of those not using devices. Nearly two-thirds (63.9 percent) of device users are unable to perform their major activity, and an additional 20.3 percent are limited in the amount or kind of major activity they can perform (the corresponding figures for the remainder of the population are 4.3 and 5.0 percent, respectively). Wheelchair, scooter, walker, and cane users all have activity limitation rates greater than 90 percent. All of these groups have high rates of inability to perform the major activity, ranging from 66 to 78 percent.

Among elderly mobility device users, the vast majority (85 percent) are over 69 years of age and are therefore treated in the NHIS as if their major activity were caring for themselves and managing their homes (ADLs and IADLs; see below). Persons unable to perform these activities are considered to have fairly severe disabilities. It is therefore not surprising that a significant majority of elderly mobility device users consider themselves able to perform their major activity. Thus, while 81.4 percent of elderly mobility device users are limited in activity (compared to 30.6 percent of those not using mobility devices), only 33.0 percent are unable to perform their major activity (vs. 6.6 percent of non-users). Wheelchair users are significantly more likely than other device users to be unable to perform their major activity, with two-thirds (66.2 percent) reporting this rather severe level of limitation. At the other extreme, only one-quarter (25.0 percent) of elderly cane users are unable to perform their major activity.

Functional Limitation

Respondents to the NHIS-D who are at least 18 years of age are asked about any difficulty they might have in eight areas of mobility-related function: lifting a ten-pound object (“lifting something as heavy as 10 pounds, such as a bag of groceries”), climbing a flight of stairs (“walking up 10 steps without resting”), walking one-quarter mile (“walking a quarter of a mile—about 3 city blocks”), standing (“for about 20 minutes”), bending (“bending down from a standing position to pick up an object from the floor, for example, a shoe”), reaching (“reaching up or over the head or reaching out as if to shake someone’s hand”), grasping (“using fingers to grasp or handle something, such as picking up a glass from the table”), and holding a pen or pencil. For each of these

Figure 10. Proportion of mobility device users and non-users limited in activity, by age and device.

items, the degree of difficulty is ascertained (some difficulty, a lot of difficulty, or completely unable). We classified those with some or a lot of difficulty as having “difficulty only” with the given function; those answering “completely unable” are classified as unable to perform the function.

To obtain a summary measure of functional limitation, we estimated the population with any degree of limitation in any of the eight functions in Tables 5-7 (“Limited in 1 or more mobility-related functions”), as well as those unable to perform at least one of the eight functions (“Unable to perform

1 or more functions”). Figure 11 shows the proportion of the population in both of those classifications for each of the mobility devices; also shown is the proportion of the population able to perform all of the functions but limited in at least one of them (“Difficulty only”).

As one might expect, the vast majority (88.7 percent) of mobility device users experience mobility-related functional limitation. Mobility device users are 8.5 times as likely to be limited in function

as persons who do not use mobility devices (10.4 percent of whom are limited in function). They are 25 times as likely to be unable to perform one or more of the mobility-related functions as the remainder of the population (54.3 vs. 2.2 percent).

At least four-fifths of the users of each of the mobility devices are classified as having some degree of functional limitation. Wheelchair, scooter, and walker users have the highest likelihood of limitation (96.2, 98.4, and 95.4 percent, respective-

Figure 11. Proportion of mobility device users and non-users with functional limitations, by degree of limitation and device, ages 18 and above.

Figure 12. Proportion of mobility device users with functional limitations, by degree and type of limitation, ages 18 and above.

ly). Some 87.3 percent of cane users report functional limitation, as do 81.8 percent of users of crutches.

The variation in the degree of functional limitation is much more pronounced. More than four-fifths of wheelchair users (85.7 percent) are unable to perform one or more of the eight functions, compared to less than half (46.1 and 45.4 percent, respectively) of cane and crutch users. Looked at another way, only 14.3 percent of wheelchair users are able to perform all of the eight mobility-related functions, compared to more than half of cane and crutch users. One-quarter (25.5 percent) of walker users report being able to perform all of the eight functions.

Figure 12 shows the proportion of the mobility device-using population with limitations in each of the eight functions. Device users are most likely to be limited in walking, with more than three-quarters (77.1 percent) having some degree of difficulty with this function and more than four-tenths (43.1 percent) unable to walk one-quarter mile. In each of the following functions, a majority of device users report limitation: climbing stairs (65.4 percent have trouble climbing a flight of stairs without resting), standing for long periods of time (64.8 percent have trouble standing for 20 minutes), bending down (60.8 percent have trouble bending from a standing position), or lifting (51.5 percent have trouble lifting a ten-pound object).

Wheelchair users are more likely to have trou-

ble in every one of the eight functional limitations than mobility device users overall. As shown in Figure 13, more than nine-tenths (94.2 percent) of wheelchair users report trouble walking, and more than three-quarters (78.5 percent) are unable to walk a quarter of a mile. Limitations in climbing, standing, and bending are also reported more than four-fifths of the time (88.4, 86.8, and 81.2 percent, respectively), and inability to climb ten stairs without resting, stand for 20 minutes, and bend down from a standing position are reported more than half the time (63.7, 61.0, and 55.4 percent). More than two-thirds (71.3 percent) report some degree of limitation in lifting ten-pound objects, and about one-third report limitation in each of the two hand-related activities measured: grasping objects (33.7 percent) and holding a pen or pencil (31.6 percent).

Activities of Daily Living

Respondents to the NHIS-D who are at least 5 years of age are asked about a set of six self-care activities, known in the literature as Activities of Daily Living (ADL): bathing or showering; dressing; eating; getting in or out of bed or chairs (which we label “transferring”); using the toilet, including getting to the toilet (“toileting”); and getting around inside the home. The following facts are ascertained about each of these activities: whether the person gets help from another person to perform the activity “because of a physical, mental, or emotional

Figure 13. Proportion of wheelchair users with functional limitations, by degree and type of limitation, ages 18 and above.

problem”; whether the person needs to be reminded to do the activity or to have someone close by “because of a physical, mental, or emotional problem”; whether the person uses special equipment to do the activity; and whether the person has difficulty with the activity “because of a physical, mental, or emotional problem.” If the person needs assistance, reminding, supervision, or special equipment to perform an ADL, it is assumed that the person has difficulty, without the question being asked.

In Tables 5–7, we have classified those persons getting help from another person, needing reminding, and needing someone close by under “needs assistance” with the activity in question. Persons with any level of difficulty with an activity, including those using special equipment, getting help, or needing reminders or someone close by, are classified as having a limitation in the activity. For summary measures of ADL limitation, we estimated the population with any level of limitation in any of the ADLs and the population needing assistance from another person (gets help, needs reminding, or needs someone close by) in one or more of the ADLs.

Figure 14 shows the proportion of mobility device users who have ADL limitations (any level of limitation in one or more ADLs), who need assistance in one or more ADLs (“Needs help”), and who have limitations but do not need assistance (“Difficulty only”). Nearly half (47.2 percent) of mobility device users have some degree of limitation in at least one ADL, compared to only 1.1 per-

cent of persons who do not use mobility devices. Almost one-third (30.9 percent) of device users need assistance from another person in ADLs, compared to only 0.7 percent of non-users. A mobility device user is 44 times as likely to report an ADL limitation as a person who does not use a mobility device and 42 times as likely to need assistance from another person in ADLs.

In fact, the 2.9 percent of Americans at least 5 years of age who use mobility devices constitute a significant majority of those with ADL limitations. Of the 5.7 million with ADL limitations, 56.2 percent, or 3.2 million people, use mobility devices. Of the 3.8 million needing personal assistance, 55.0 percent are mobility device users, or 2.1 million persons.

Wheelchair users are the most limited in ADLs, with four-fifths (80.2 percent) reporting some degree of difficulty in at least one ADL and more than three-fifths (62.7 percent) needing assistance in at least one ADL. Walker and scooter users are also very likely to be limited in ADLs, with 72.1 and 71.3 percent reporting limitation, respectively, and 50.0 and 37.3 percent reporting assistance needs. Least likely to be limited in ADLs are cane users, of whom 37.8 are limited and only 22.0 percent need assistance from another person.

Figure 15 shows the proportion of mobility device users with limitations in specific ADLs. Bathing is the activity most likely to present difficulty to device users, with more than one-third (37.9 percent) reporting some degree of limitation in

Figure 14. Proportion of mobility device users and non-users with ADL limitations, by degree of limitation and device, ages 5 and above.

bathing. Bathing and dressing are the activities for which mobility device users are most likely to need assistance (26.7 and 20.7 percent, respectively), followed by transferring at 17.0 percent. Only 7.7 percent of mobility device users have difficulty eating.

Wheelchair users are more likely to report limitation in each of the ADLs (Figure 16) than are mobility device users overall. Again, bathing is the activity most likely to present problems (72.0 percent are limited in bathing). A majority of wheelchair users are limited in dressing (54.6 percent), transferring (55.4 percent), toileting (52.6 percent), and getting around inside the home (59.6 percent). Again, eating is the ADL least likely to present

problems (23.3 percent limited).

Assistance is most often needed in bathing (58.4 percent of wheelchair users), dressing (50.0 percent), and transferring (43.7 percent). More than one-third of wheelchair users need help with getting around inside (37.6 percent), and a similar proportion need assistance in toileting (37.5 percent). Wheelchair users are relatively unlikely to need assistance with eating (20.1 percent).

Instrumental Activities of Daily Living

The Instrumental Activities of Daily Living (IADL) are a set of everyday activities associated

Figure 15. Proportion of mobility device users with ADL limitations, by degree and type of limitation, ages 5 and above.

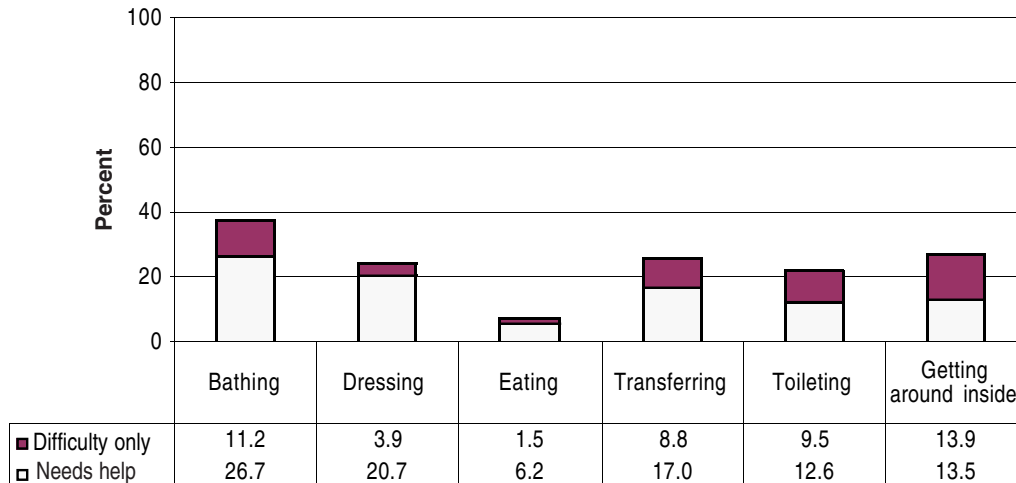

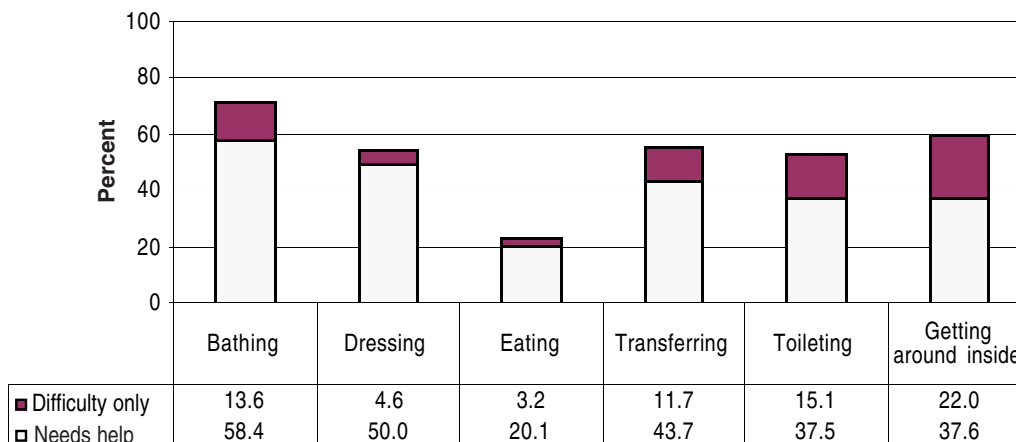

Figure 16. Proportion of wheelchair users with ADL limitations, by degree and type of limitation, ages 5 and above.

with managing a home. The NHIS-D asks about these IADLs for persons aged 18 or over: preparing meals, shopping (“for personal items, such as toilet items or medicine”), managing money (“such as keeping track of expenses or paying bills”), using the telephone, doing heavy housework (“heavy work around the house like scrubbing floors, washing windows, and doing heavy yard work”), and doing light housework (“light work around the house like doing dishes, straightening up, light cleaning, or taking out the trash”). For each activity, the following information is obtained: whether the person gets help or supervision from another person in performing the activity “because of a physical, mental, or emotional problem” and whether the person has

difficulty performing the activity “because of a physical, mental, or emotional problem.” Again, difficulty is assumed if the person needs help or supervision.

More than two-thirds (68.1 percent) of mobility device users have one or more IADL limitations, compared to only 5.5 percent of those not using mobility devices (Figure 17). The vast majority of those limited in IADLs need assistance in at least one IADL (62.0 percent of mobility device users are reported as getting help or supervision, compared to 4.6 percent of non-users). Wheelchair, scooter, and walker users are the most likely to have IADL limitations, with more than four-fifths of each group reporting limitation (86.4, 87.1, and 82.6 percent, respectively) and more than three-quarters of

Figure 17. Proportion of mobility device users and non-users with IADL limitations, by degree of limitation and device, ages 18 and above.

Figure 18. Proportion of mobility device users with IADL limitations, by degree and type of limitation, ages 18 and above.

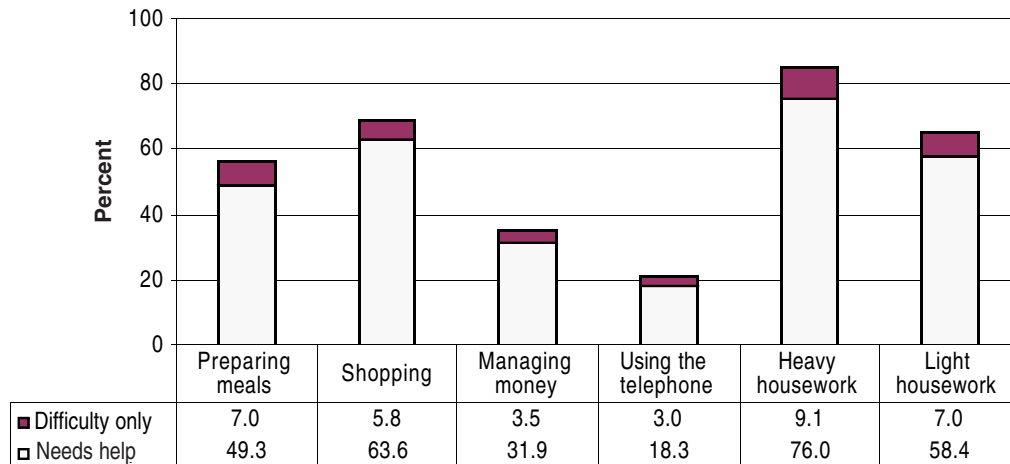

Figure 19. Proportion of wheelchair users with IADL limitations, by degree and type of limitation, ages 18 and above.

each group needing help in IADLs (80.6, 80.6, and 77.0 percent). A majority of cane and crutch users have IADL limitations (63.5 and 62.2 percent, respectively), most of whom need assistance (57.2 and 55.7 percent of the users of those devices).

As shown in Figure 18, heavy housework is the IADL in which mobility device users are most likely to experience limitation, with two-thirds (66.0 percent) reporting some degree of limitation and more than half (58.4 percent) needing help in this activity. Device users are far less likely to report limitation in the other IADLs. Shopping (39.9 percent), light housework (34.1 percent), and preparing meals (26.2 percent) are the only other IADLs in which limitation affects one-quarter or more of device users in general.

Wheelchair users (Figure 19) are very likely to be limited in heavy housework: 85.1 percent are

limited to some degree and 76.0 percent need help performing this IADL. Limitations in shopping and light housework are reported by about two-thirds of wheelchair users (69.4 and 65.4 percent, respectively), and a substantial majority need help in these activities (63.6 and 58.4 percent). A limitation in preparing meals is also reported by a majority of wheelchair users (56.3 percent); half (49.3 percent) need help in this activity.

Overall, three-quarters (73.1 percent) of mobility device-using adults and nine-tenths (92.1 percent) of wheelchair-using adults experience some degree of limitation in at least one of the self-care or home-management activities (ADLs or IADLs). Some 65.9 percent of adults who use mobility devices need assistance from another person in one or more of the activities, as do 86.7 percent of adults who use wheelchairs.

HEALTH CONDITIONS AND IMPAIRMENTS ASSOCIATED WITH MOBILITY DEVICE USE

Tables 8 through 10 list the principal health conditions and impairments associated with the use of mobility devices. Because respondents to the NHIS-D are not asked to specify the condition that necessitates their use of a mobility device, it is not possible to directly attribute a person’s device use to a particular condition. Instead, the conditions listed are those mentioned by respondents as the main cause of their disability, defined in terms of either functional or activity limitation, as described below.

There are two sources of relevant condition information available in the survey, one in the NHIS-D and one in the NHIS core. The former is obtained by asking those adult (18 years of age or older) respondents who indicate that they have one or more mobility-related functional limitations to indicate the main cause of that limitation. The latter is obtained by asking all respondents limited in any activity to specify all conditions that limit their activity; they are then asked to identify the main condition causing their activity limitation. In Tables 8–10, we have used the condition causing functional limitation whenever it is available (namely, for adults with functional limitations that have been captured in the survey); when no information about the condition causing functional limitation is available (for children and adults without identified functional limitations), the main condition

causing activity limitation has been used instead.

Conditions have been classified according to the scheme developed in LaPlante and Carlson (1996). We have listed the subset of specific conditions, along with a few broader categories of conditions, whose prevalence among mobility device users is sufficient to yield statistically reliable population estimates for persons with that condition using any mobility device. Because all condition information is self-reported, and because interviewers do not attempt to elucidate additional details once a condition is stated, specific conditions may tend to be undercounted in the survey in favor of broader, catch-all categories. For example, a person reporting merely “heart trouble” cannot be classified as having a specific condition such as angina or hypertensive disease, but instead would be coded under the category “other forms of heart disease.”

Table 8 shows the principal conditions associated with mobility device use for all ages; Table 9 shows the conditions for working-age adults (aged 18–64) and Table 10 shows conditions associated with mobility device use among elderly persons.

All Ages

Table D ranks the leading ten conditions associated with mobility device use among persons of

Table D. Leading conditions[†] associated with mobility device use, all ages.

Condition	Persons (1000s)	Proportion of device users (%)
All conditions	6,321	100.00
1 Osteoarthritis and allied disorders	1,189	18.81
2 Cerebrovascular disease	442	6.98
3 Orthopedic impairment of lower extremity	367	5.80
4 Orthopedic impairment of back or neck	273	4.32
5 Intervertebral disc disorders	237	3.75
6 Senility without mention of psychosis	236	3.73
7 Other forms of heart disease	210	3.32
8 Rheumatoid arthritis and other inflammatory polyarthropathies	201	3.18
9 Orthopedic impairment of hip and/or pelvis	185	2.92
10 Chronic injuries or late effects of injuries	131	2.07

[†]Conditions reported as the main cause of functional or activity limitation (see text).

all ages. These conditions account for more than half (54.9 percent) of mobility device use. Osteoarthritis is by far the most prevalent condition, affecting 1.2 million mobility device users as the primary cause of disability and accounting for 18.8 percent of mobility device use. Next are cerebrovascular disease (affecting 442,000 persons) and orthopedic impairments of the lower extremity (367,000), followed by two conditions related to the back: orthopedic impairments of the back or neck (273,000), and intervertebral disc disorders (237,000 persons). These two back-related conditions, taken together, are responsible for disability in 0.5 million mobility device users.

Table E lists the top-ranked conditions associ-

ated with wheelchair or scooter use. Just under half (49.3 percent) of wheelchair/scooter users specify one of the ten listed conditions as their primary cause of disability. Cerebrovascular disease (likely to be reported as "stroke"), which affects 180,000 wheelchair/scooter users, and osteoarthritis, affecting 170,000 persons, are the two most prevalent primary conditions among this group. Although these conditions are commonly associated with aging, other highly prevalent conditions are not: multiple sclerosis (82,000 persons), absence or loss of lower extremity (60,000), paraplegia (59,000), and orthopedic impairments of lower extremity (59,000).

Because of the relatively small numbers of

Table E. Leading conditions[†] associated with wheelchair or scooter use, all ages.

Condition	Persons (1000s)	Proportion of device users (%)
All conditions	1,629	100.00
1 Cerebrovascular disease	180	11.05
2 Osteoarthritis and allied disorders	170	10.43
3 Multiple sclerosis	82	5.02
4 Absence or loss of lower extremity	60	3.68
5 Paraplegia (paralysis of both legs)	59	3.63
6 Orthopedic impairment of lower extremity	59	3.62
7 Other forms of heart disease	54	3.30
8 Cerebral palsy	51	3.11
9 Rheumatoid arthritis and other inflammatory polyarthropathies	49	3.00
10 Diabetes	39	2.40

[†]Conditions reported as the main cause of functional or activity limitation (see text).

Table F. Leading conditions[†] associated with cane use, all ages.

Condition	Persons (1000s)	Proportion of device users (%)
All conditions	4,384	100.00
1 Osteoarthritis and allied disorders	976	22.26
2 Cerebrovascular disease	294	6.70
3 Orthopedic impairment of lower extremity	270	6.17
4 Orthopedic impairment of back or neck	226	5.16
5 Intervertebral disc disorders	218	4.97
6 Senility without mention of psychosis	172	3.92
7 Other forms of heart disease	152	3.46
8 Rheumatoid arthritis and other inflammatory polyarthropathies	142	3.23
9 Orthopedic impairment of hip and/or pelvis	132	3.00
10 Absence or loss of rib, bone, joint, or muscle of trunk	100	2.29

[†]Conditions reported as the main cause of functional or activity limitation (see text).

people using electric wheelchairs and scooters, it is not possible to present statistically reliable prevalence estimates of conditions associated specifically with the use of these two devices. It is possible, however, to note broad differences among conditions associated with the use of manual wheelchairs, electric wheelchairs, and scooters. While manual wheelchair users are most likely to have age-related diseases of the circulatory or musculoskeletal system, electric wheelchair users are most likely to have some form of paralysis, such as quadriplegia, cerebral palsy, or paraplegia. These forms of paralysis are not highly associated with scooter use, however; instead, scooter users are most likely to have diseases of the nervous system, such as multiple sclerosis and amyotrophic lateral sclerosis, or diseases of the musculoskeletal system, such as osteoarthritis, rheumatoid arthritis, and spondylosis.

Osteoarthritis is the top-ranked condition responsible for disability among users of both canes and walkers (Tables F and G). More than one-fifth (22.3 percent) of cane users and nearly one-fifth (19.1 percent) of walker users mention osteoarthritis as the main cause of functional or activity limitation, or 976,000 and 335,000 persons, respectively. For both cane and walker users, cerebrovascular disease and orthopedic impairments of the lower extremity are also highly prevalent. Cerebrovascular disease is the primary cause of disability among 294,000 cane users and 136,000 walker users; orthopedic impairment of the lower extremity affects 270,000 cane users and 91,000 walker users. Back problems, senility, heart dis-

ease, hip problems, and rheumatoid arthritis are also prevalent among both cane and walker users.

The top four conditions associated with the use of crutches (Table H) all have similar prevalence: osteoarthritis is the main cause of disability for 59,000 crutch users; orthopedic impairments of the lower extremity affect 55,000 persons; absence or loss of lower extremity affects 47,000 persons; and late effects of injury are the main cause of limitation among 40,000 crutch users.

Leading Conditions by Age Group

Osteoarthritis, the most prevalent main cause of disability among mobility device users at all ages, remains the leading condition for both of the age groups shown in Tables I and J. Among working-age adults, it is the primary cause of disability for 228,000 persons, accounting for 10.5 percent of mobility device use; among the elderly, osteoarthritis is responsible for a much larger proportion (23.7 percent) of mobility device use, affecting 957,000 persons.

Among working-age adults, the next three conditions all have similar prevalences: intervertebral disc disorders are the primary cause of disability among 176,000 mobility device users; orthopedic impairments of the back or neck affect 162,000 persons; and orthopedic impairments of the lower extremity affect 140,000 persons. Taken together, the two back-related conditions (disc disorders and orthopedic impairments) are responsible for mobility device use among 337,000 persons, making the general category of “back

Table G. Leading conditions[†] associated with walker use, all ages.

Condition	Persons (1000s)	Proportion of device users (%)

[†]Conditions reported as the main cause of functional or activity limitation (see text).

problems" even more prevalent than osteoarthritis in this group.

Among the elderly, cerebrovascular disease ranks a distant second to osteoarthritis, affecting 342,000 persons as the primary cause of disability. Next are senility, affecting 233,000 persons, and orthopedic impairments of the lower extremity, which affect 226,000 elderly mobility device users. Heart disease, hip problems, back problems, and rheumatoid arthritis are also

prevalent in this group.

The most prevalent main conditions associated with wheelchair/scooter use among working-age adults (Table K) are multiple sclerosis (58,000 persons), paraplegia (45,000), and cerebrovascular disease (44,000). Among the elderly (Table L), 30 percent of wheelchair/scooter users cite either osteoarthritis (139,000 persons) or cerebrovascular disease (136,000) as their primary cause of functional or activity limitation.

ACCESSIBILITY FEATURES AND PROBLEMS

In the Disability Followback Survey (DFS), Phase II of the National Health Interview Survey on Disability, adult respondents are asked various questions about their environments. Questions focus on features in the home that might make it more accessible to persons limited in mobility, as well as on difficulties in using the home, difficulties encountered outside the home, and difficulties associated with using public transportation.

Population estimates of mobility device users having such accessibility features and encountering such difficulties are presented in Tables 11–13, along with the proportion of users of each device who have accessibility features or encounter access problems. For comparison, statistics are also presented on persons in the DFS sample who are not mobility device users; note that these estimates are not representative of the non-device-using population in general, but only of the subset of adults who would be eligible to participate in the

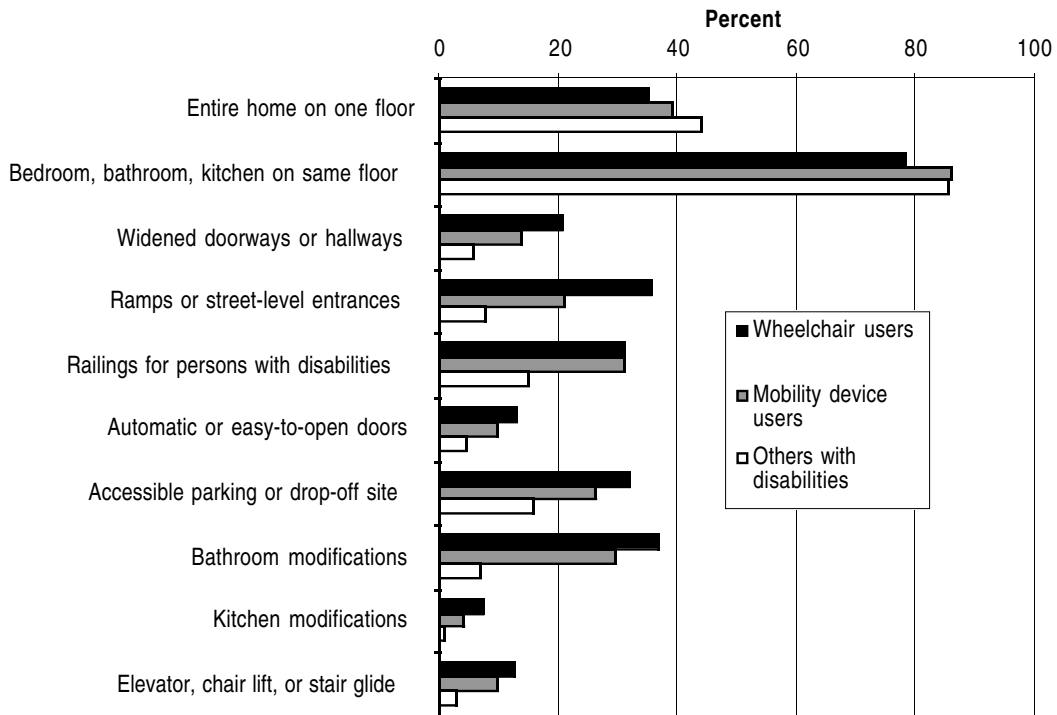

DFS, based on an actual or potential disability (see Data Source and Accuracy). Table 11 presents statistics for adults of any age. Table 12 contains data for working-age adults, and Table 13 presents data for elderly adults.

Within and Around the Home

As Figure 20 shows, a minority of mobility device users (39.3 percent) live in homes with all rooms on one level (“counting basements and step-down living areas as separate levels”). But more than four-fifths of device users (85.8 percent) live in homes with a bedroom, a bathroom, and the kitchen all on the same floor.

In response to questions about “special features to assist persons who have physical impairments or health problems,” only a relatively small proportion of mobility device users responded affirmatively to each of the features mentioned.

Figure 20. Proportion of mobility device users and non-users with home accessibility features, by type of feature and device, ages 18 and above.

Device users in general are most likely to have railings as an accessibility feature (31.0 percent), bathroom modifications (29.6 percent), or accessible parking (26.4 percent). Ramps or street-level entrances are the next most common accessibility feature among device users (21.0 percent), with the remaining features considerably less likely to be found in the home: automatic or easy-open doors (9.7 percent); elevator, chair lift, or stair glide (9.6 percent), and kitchen modifications (4.0 percent).

Wheelchair users are more likely than device users overall to have accessibility features: bathroom modifications, ramps or street-level entrances, accessible parking, and railings are each mentioned about one-third of the time (36.5, 35.5, 32.0 and 31.2 percent, respectively). Widened doorways or hallways are a feature in 20.6 percent of wheelchair users' homes. Again, the remaining features occur considerably less often: automatic or easy-open doors (12.8 percent); elevator, chair lift, or stair glide (12.7 percent), and kitchen modifications (7.4 percent).

Bathroom modifications are the accessibility feature most likely to be reported as needed but not present in the homes of mobility device users (Table 11). Some 8.9 percent of device users and 11.6 percent of wheelchair users lack this needed feature.

Although the vast majority of mobility device users can move between the essential rooms of

their homes without using steps, leaving the home presents much more of a problem. As shown in Figure 21, a majority of mobility device users (62.1 percent) and half of wheelchair users (49.2 percent) must use steps to enter or exit their homes. A slight majority of wheelchair users (52.1 percent) and two-fifths of mobility device users in general (40.2 percent) report having difficulty entering or leaving the home. And even within the home, problems are frequently encountered: 47.0 percent of wheelchair users and 31.9 percent of mobility device users have difficulty reaching or opening cabinets; 35.5 percent of wheelchair users and 19.2 percent of mobility device users have difficulty using the bathroom; and 33.1 percent of wheelchair users and 16.3 percent of mobility device users have difficulty opening or closing doors in the home.

Outside the Home

Outside the home, one-third of wheelchair and scooter users (33.2 and 34.1 percent, respectively) report wheelchair accessibility problems (see Table 11). These figures exclude problems involving public transportation, which is the subject of a separate set of questions. Users of other devices are much less likely to report accessibility problems with those devices: only 3.2 percent of mobility device users report problems with assistive devices other than wheelchairs.

Figure 21. Proportion of mobility device users and non-users with home accessibility difficulties, by type of difficulty and device, ages 18 and above.

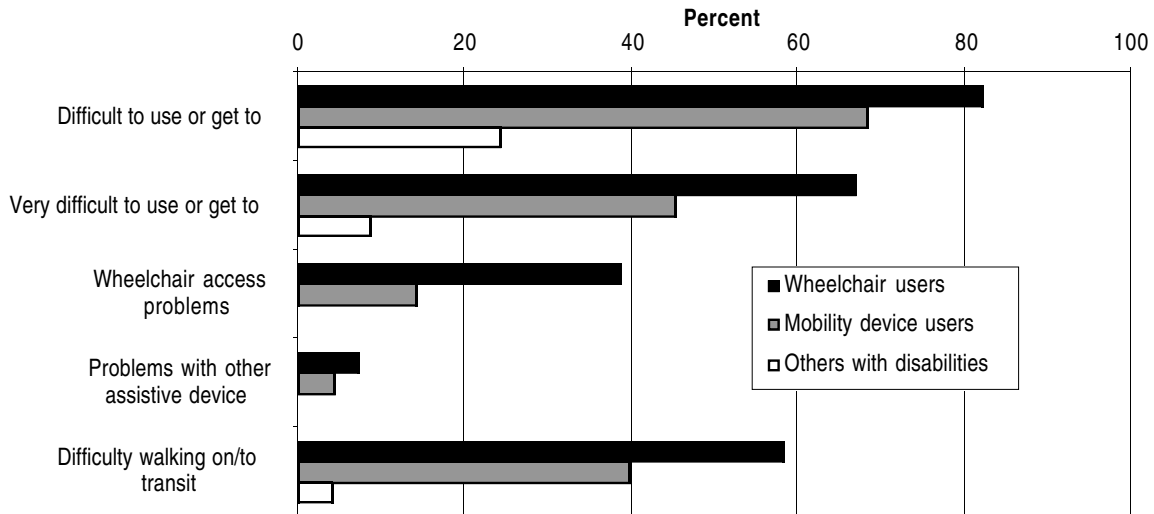

Figure 22. Proportion of mobility device users and non-users experiencing public transportation difficulties, by type of difficulty and device, ages 18 and above.

Note: Statistics exclude persons living in areas without public transportation systems.

Public Transportation

Four-fifths of wheelchair users (82.0 percent) report that their local public transportation system is difficult to use or to get to (see Figure 22); two-thirds (66.9 percent) say it is very difficult to use or get to. Among mobility device users in general, the proportions are two-thirds (68.3 percent) reporting difficulty and nearly one-half

(45.2 percent) reporting “very difficult” access. Some 38.7 percent of wheelchair users specifically report wheelchair access problems, and 39.9 percent of mobility device users and 58.1 percent of wheelchair users report that difficulty walking is or would be a problem for them in using public transit. Device users living in areas without public transportation systems have been excluded from these statistics.

HEALTH INSURANCE

Respondents to Phase I of the NHIS-D were also asked about health insurance coverage during the same interview, as part of the NHIS Family Resources Supplement. Table 14 presents population estimates for mobility device users and non-users who are covered by various public and private health insurance plans.⁵ Note that many people have more than one source of health insurance; thus, the categories are not mutually exclusive.

As shown in Figure 23, mobility device users in all age categories are very likely to have some form of health insurance. Roughly one-tenth of children and working-age adults who use mobility devices are uninsured (9.6 and 12.5 percent, respectively), while less than 1 percent of elderly device users lack some form of coverage. Public health insurance programs are crucial to mobility device users in all age groups. Among children,

46.2 percent are covered under Medicaid, compared to 48.1 percent with private insurance. And among working-age adults, 45.8 percent have private coverage, or about half of those with insurance. One-third (33.6 percent) of working-age device users are covered under Medicare and one-quarter (25.5 percent) under Medicaid. Among the elderly, the vast majority (95.3 percent) are covered under Medicare, but many also have private plans (65.7 percent of elderly mobility device users), in many cases so-called Medigap plans.

Wheelchair users are even more likely to be covered under public insurance than are mobility device users overall (see Figure 24). Among children, 58.9 percent are covered under Medicaid, while only 36.9 percent have private insurance. Working-age wheelchair users are covered under Medicare 41.9 percent of the time, private insurance 45.1 percent, and Medicaid 31.8 percent of the time. Among the elderly, 94.7 percent of wheelchair users are covered under Medicare, with private insurance plans held by 61.2 percent of this population.

⁵ Respondents with unknown health insurance status (non-response to the Family Resources Supplement) have been excluded from the tabulations. Thus, overall population estimates in Table 14 are slightly lower than those in Tables 1-4.

Figure 23. Health insurance coverage of mobility device users, by age and type of coverage.

Figure 24. Health insurance coverage of wheelchair users, by age and type of coverage.

CONCLUSIONS

As a group, the 6.8 million community-resident Americans who use mobility devices differ in many significant ways from the population at large. They experience severe functional and activity limitations in much greater proportions, and they are more than 40 times as likely to need assistance with self-care activities as their counterparts who do not use mobility devices. A majority are in poor or indifferent health, and many have experienced a recent hospitalization. Many are affected by debilitating health conditions, such as arthritis, stroke, or serious back problems; others have long-term conditions and impairments, such as multiple sclerosis or some form of paralysis.

A majority of the population using mobility devices is elderly, but there is a substantial minority who are of working-age. Members of this group are very unlikely to have jobs and, partly as a consequence, are substantially more likely than the remainder of the population to live in poverty. At all ages, income levels for mobility device users tend to be low, as do levels of educational attainment.

Women are more likely to use mobility devices than men, and African Americans more likely than whites, who are in turn much more likely than Asians and Pacific Islanders to be device users. Latinos are less likely to use mobility devices than people not of Hispanic origin.

Most mobility device users, especially those using wheelchairs and scooters, perceive themselves as having disabilities. Given the extent of functional and activity limitation they experience, this fact comes as no surprise. But to the extent that disability is seen as a result of environmental factors, the high rate of self-identification as disabled is even more easily understood. This report provides ample evidence that mobility device users face access barriers on a daily basis. A majority of device users, for example, cannot leave their homes without using steps; half of wheelchair users face the same obstacle. Few have the home accessibility features that would facilitate basic household tasks, not to mention moving about inside. And the vast majority report difficulty with public transit; for many, the difficulty is insurmountable.

Despite recent changes in society that have led to greater attention to environmental accessibility and to opportunities for employment and independent living for people with disabilities, it remains clear that the population using mobility devices continues to face substantial challenges in achieving these goals.

Source: Disability Followback Survey, 1994–97

[†] Estimates in Tables 11–13 are based on answers to questions about mobility device use from the Disability Followback Survey, Phase II of the National Health Interview Survey on Disability. Because of the time lag between interviews, statistics presented in the previous tables, which are based on questions from Phase I, should be considered slightly more reliable as overall estimates of mobility device use.

[‡] Excludes public transportation.

[‡] Includes only persons who would qualify to be interviewed in the Disability Followback Survey. Not representative of the overall population of non-device-users.

* Estimate has low statistical reliability (standard error exceeds 30 percent of estimate).

Source: Disability Followback Survey, 1994–97

[†]Estimates in Tables 11–13 are based on answers to questions about mobility device use from the Disability Followback Survey, Phase II of the National Health Interview Survey on Disability. Because of the time lag between interviews, statistics presented in the previous tables, which are based on questions from Phase I, should be considered slightly more reliable as overall estimates of mobility device use.

[‡]Excludes public transportation.

[‡]Includes only persons who would qualify to be interviewed in the Disability Followback Survey. Not representative of the overall population of non-device-users.

*Estimate has low statistical reliability (standard error exceeds 30 percent of estimate).

Table 13. Prevalence of home accessibility features and environmental accessibility difficulties among mobility device users and non-users, by type of device: United States civilian noninstitutionalized population, ages 65 and above.
